

# Algorithms and Analysis

## Lesson 17: *Sort Wisely*

*Merge sort, quick sort and radix sort*

# Outline

1. **Merge Sort**
2. Quick Sort
3. Radix Sort

# Merge Sort

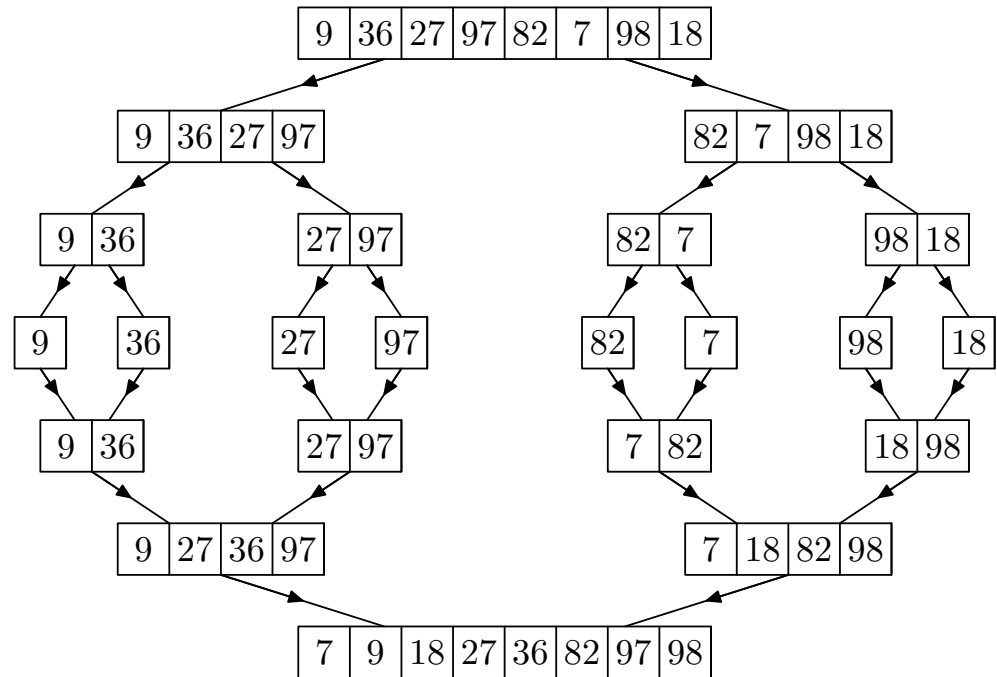

- Merge sort is an example of sort performed in log-linear (i.e.  $O(n \log(n))$ ) time complexity■
- It was invented in 1945 by John von Neumann■
- It is an example of a divide-and-conquer strategy■
  - ★ That is, the problem is divided into a number of parts recursively■
  - ★ The full solution is obtained by recombining the parts■

# Algorithm

```

MERGESORT(a)
{
  if n > 1
    copy a[1 : ⌊n/2⌋] to b
    copy a[⌊n/2⌋ + 1 : n] to c
    MERGESORT(b)
    MERGESORT(c)
    MERGE(b, c, a)
  endif
}

```

# Merge

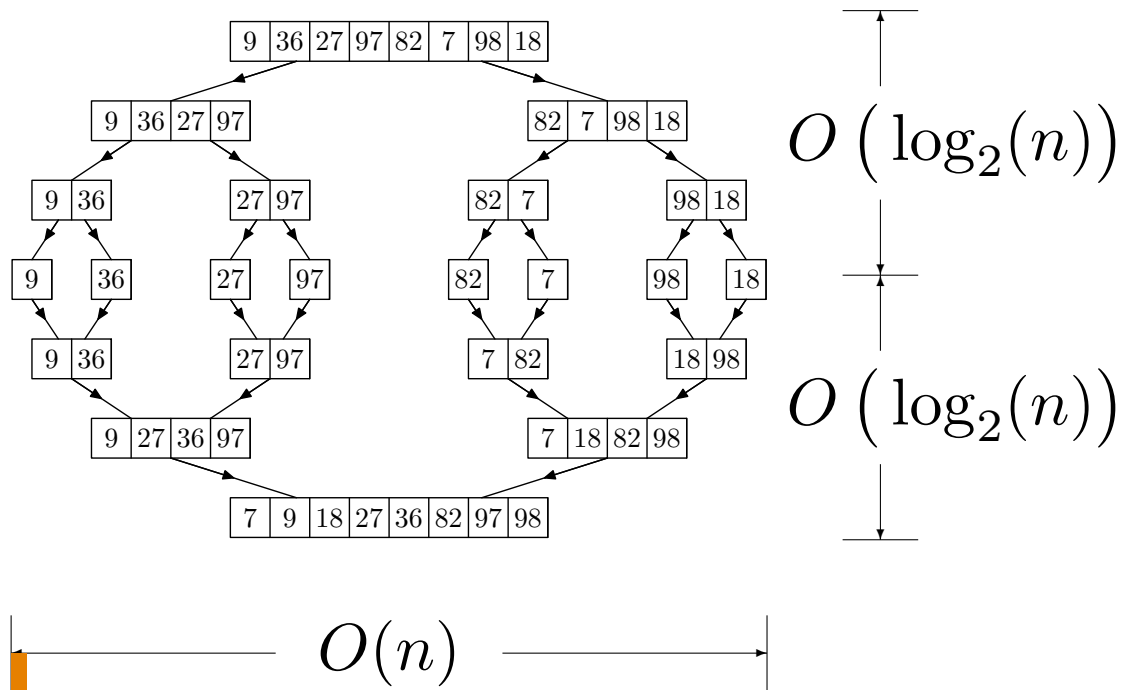

```
MERGE ( $\mathbf{b}[1 : p], \mathbf{c}[1 : q], \mathbf{a}[1 : p + q]$ )  
{  
   $i \leftarrow 1$   
   $j \leftarrow 1$   
   $k \leftarrow 1$   
  while  $i \leq p$  and  $j \leq q$  do  
    if  $b_i \leq c_j$   
       $a_k \leftarrow b_i$   
       $i \leftarrow i + 1$   
    else  
       $a_k \leftarrow c_j$   
       $j \leftarrow j + 1$   
    endif  
     $k \leftarrow k + 1$   
  end  
  if  $i = p$   
    copy  $\mathbf{c}[j : q]$  to  $\mathbf{a}[k : p + q]$   
  else  
    copy  $\mathbf{b}[i : p]$  to  $\mathbf{a}[k : p + q]$   
  }
```

# Properties of Merge Sort

- Merge sort is stable provided we merge carefully (i.e. it preserves the order of two entries with the same value)■
- Merge sort isn't in-place■—we need an array of at most size  $n$  to do the merging■
- Merging is quick.■ Given two arrays of size  $n$  the most number of comparisons we need to perform is  $n - 1$ ■

# Time Complexity of Merge Sort

$$n = 8$$

# Time Complexity of Merge Sort

# Time Complexity

- We again measure the complexity in the number of comparisons■
- From the above argument  $C(n) = O(n \times \log_2(n))$ ■
- We can be a bit more formal

$$C(n) = 2C(\lfloor n/2 \rfloor) + C_{\text{merge}}(n) \quad \text{for } n > 1$$

$$C(0) = 1$$

- But in the worst case  $C_{\text{merge}}(n) = n - 1$ ■
- Leads to  $C_{\text{worst}}(n) = n \log_2(n) - n + 1$ ■

# General Time Complexity

- In general if we have a recursion formula

$$T(n) = aT(n/b) + f(n) \blacksquare$$

with  $a \geq 1, b > 1$  ■

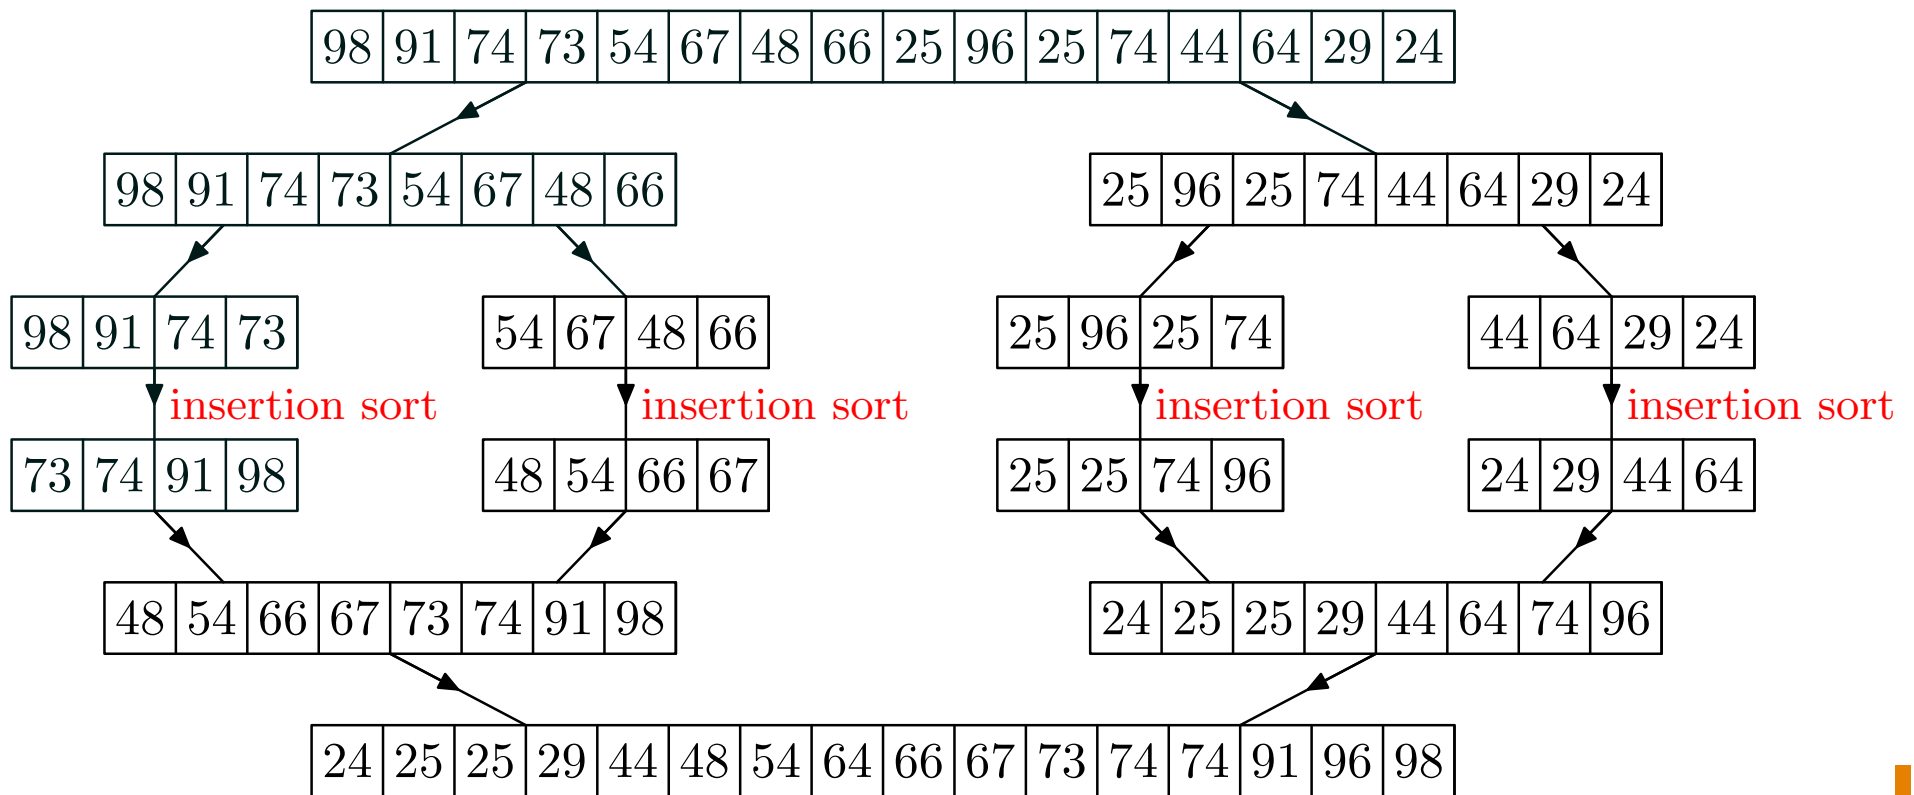

- If  $f(n) \in \Theta(n^d)$  where  $d \geq 0$  then

$$T(n) \in \begin{cases} \Theta(n^d) & \text{if } a < b^d \\ \Theta(n^d \log(n)) & \text{if } a = b^d \\ \Theta(n^{\log_d(a)}) & \text{if } a > b^d \end{cases} \blacksquare$$

- Analogous results hold for the family  $O$  and  $\Omega$  ■

# Mixing Sort

- For very short sequences it is faster to use insertion sort than to pay the overhead of function calls

# Outline

1. Merge Sort
2. **Quick Sort**
3. Radix Sort

# Quicksort

- The most commonly used fast sorting algorithm is **quicksort**■
- It was invented by the British computer scientist by C. A. R. Hoare in 1962■
- It again uses the divide-and-conquer strategy■
- It can be performed in-place, but it is **not** stable■
- It works by splitting an array into two depending on whether the elements are less than or greater than a **pivot** value■
- This is done recursively until the full array is sorted■

# Partition

- We need to partition the array around the pivot  $p$  such that

|                    |                       |
|--------------------|-----------------------|
| all elements $< p$ | all elements $\geq p$ |
|--------------------|-----------------------|

```
PARTITION( $a$ ,  $p$ , left, right)
```

```
{  
   $i \leftarrow \text{left}$   
   $j \leftarrow \text{right}$   
  repeat {  
    while  $a_i < p$   
       $i++$   
    while  $a_j \geq p$   
       $j--$   
    if  $i \geq j$   
      break  
    SWAP( $a_i, a_j$ )  
  }  
}
```

pivot = 52

|    |    |    |    |    |   |    |    |    |    |    |    |    |    |    |    |
|----|----|----|----|----|---|----|----|----|----|----|----|----|----|----|----|
| 33 | 49 | 11 | 29 | 40 | 6 | 47 | 10 | 73 | 60 | 87 | 96 | 52 | 94 | 57 | 85 |
|----|----|----|----|----|---|----|----|----|----|----|----|----|----|----|----|

↑  
 $j$

# Optimising Partitioning

- There are different ways of performing the partitioning
- We want to minimise the time taken on the inner loop
- This means we want to perform as few checks as possible
- One method of doing this is to place *sentinels* at the ends of the array
- We can also reduce work by placing the partition in its correct position

# Choosing the Pivot

- There are different strategies to choosing the pivot■
- Choose the first element in the array■
- Choose the median of the first, middle and last element of the array■
- This increases the likelihood of the pivot being close to the median of the whole array■
- For large arrays (above 40) the median of 3 medians is often used■

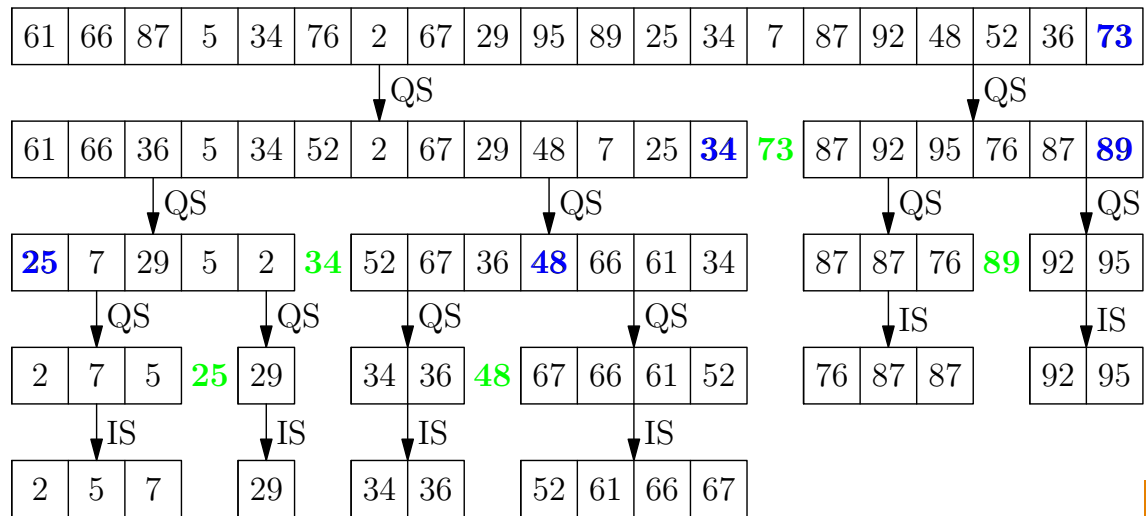

# Quicksort

We recursively partition the array until each partition is small enough to sort using insertion sort

```

QUICKSORT(a, left, right) {
    if (right-left < threshold)
        INSERTIONSORT(a, left, right)
    else
        pivot = CHOOSEPIVOT(a, left, right)
        part = PARTITION(a, pivot, left, right)
        QUICKSORT(a, left, part-1)
        QUICKSORT(a, part+1, right)
    endif
}
    
```

# Time Complexity

- Partitioning an array of size  $n$  takes  $\Theta(n)$  operations■
- If we split the array in half then number of partitions we need to do is  $\lceil \log_2(n) \rceil$ ■
- This is the best case thus quicksort is  $\Omega(n \log(n))$ ■
- If the pivot is the minimum element of the array then we have to partition  $n - 1$  times■
- This is the worst case so quicksort is  $O(n^2)$ ■
- This worst case will happen if the array is already sorted and we choose the pivot to be the first element in the array!■

# QuickSort

```

0 quickSort(a, 0, 19){
1   if(0 < 19){
2     p = choosePivot(a, 0, 19)
3     i = partition(a, p, 19)
4     quickSort(a, 0, i-1)
5     quickSort(a, i+1, 19)
6   } else
7     insertionSort(a, 0, 19)
8   return
9 }

```

|    |   |    |
|----|---|----|
| PC | = | 0  |
| l  | = | 0  |
| h  | = | 19 |
| p  | = | 0  |
| i  | = | 3  |

|    |    |    |    |    |
|----|----|----|----|----|
| 7  | 0  | 12 | #  | #  |
| 8  | 10 | 10 | 25 | 8  |
| 9  | 14 | 19 | 89 | 17 |
| 10 | 0  | 19 | 73 | 13 |

pc l h p i

|     |   |      |    |      |    |     |      |    |     |    |      |    |     |    |      |    |     |      |    |
|-----|---|------|----|------|----|-----|------|----|-----|----|------|----|-----|----|------|----|-----|------|----|
| 0   | 1 | 2    | 3  | 4    | 5  | 6   | 7    | 8  | 9   | 10 | 11   | 12 | 13  | 14 | 15   | 16 | 17  | 18   | 19 |
| 2   | 5 | 7    | 25 | 29   | 34 | 34  | 36   | 48 | 52  | 61 | 66   | 67 | 73  | 76 | 87   | 87 | 89  | 92   | 95 |
| low |   | high |    | high |    | low | high |    | low |    | high |    | low |    | high |    | low | high |    |

# Sort in Practice

- The STL in C++ offers three sorts
  - ★ `sort()` implemented using quicksort■
  - ★ `stable_sort()` implemented using mergesort■
  - ★ `partial_sort()` implemented using heapsort■
- Java uses
  - ★ Quicksort to sort arrays of primitive types■
  - ★ Mergesort to sort Collections of objects■
- Quicksort is typically fastest but has worst case quadratic time complexity■

# Selection

- A related problem to sorting is selection■
- That is we want to select the  $k^{th}$  largest element■
- We could do this by first sorting the array■
- A full sort is not however necessary■—we can use a modified quicksort where we only continue to sort the part of the array we are interested in■
- This leads to a  $\Theta(n \log(n))$  algorithm which is considerably faster than sorting■

# Outline

1. Merge Sort
2. Quick Sort
3. **Radix Sort**

# Radix Sort

- Can we get a sort algorithm to run faster than  $O(n \log(n))$ ? ■
- Our proof that this was optimal assumed we were performing binary decisions (is  $a_i$  less than  $a_j$ ?) ■
- If we don't perform pairwise comparisons then the proof doesn't apply ■
- Radix sort is the classic example of a sort algorithm that doesn't use pairwise comparisons ■

# Sorting Into Buckets

- The idea behind radix sort is to sort the elements of an array into some number of buckets■
- This is done successively until the whole array is sorted■
- Consider sorting integers in decimals (base 10 or radix 10)■
- We can successively sort on the digits■
- The sort finishes when we have got through all the digits■

# Radix Sort in Action

|    |   |      |
|----|---|------|
| 11 | 0 | null |
| 13 | 1 | null |
| 26 | 2 | null |
| 29 | 3 | null |
| 37 | 4 | null |
| 43 | 5 | null |
| 51 | 6 | null |
| 51 | 7 | null |
| 52 | 8 | null |
| 79 | 9 | null |

# Time Complexity of Radix Sort

- We need not use base 10 we could use base  $r$  (the radix)■
- If the maximum number to be sorted is  $N$  then the number of iterations of radix sort is  $\log_r(N)$ ■
- Each sort involves  $n$  operations■
- Thus the total number of operations is  $O(n \lceil \log_r(N) \rceil)$ ■
- Since  $N$  does not depend on  $n$  we can write this as  $O(n)$  ■

# Bucket Sort

- A closely related sort is bucket sort where we divide up the inputs into buckets based on the most significant figure■
- We then sort the buckets on less significant figures■
- Quicksort is a bucket sort with two buckets, but where we choose a pivot to determine which bucket to use■

# Minimum Time for Sort

- Can we do better?■
- In any sort we need to examine all possible elements in the array■
- If there is an element that isn't examined then we don't know where to put it■
- Thus the lower bound on any sort algorithm is  $\Omega(n)$ ■

# Practical Sort

- In practice, radix sort or bucket sort are rarely used■
- The overhead of maintaining the buckets make them less efficient than they might appear■
- Radix sort is harder to generalise to other data types than comparison based sorts■
- In practice quick sort and merge sort are usually preferred■
- Having said that there are some very neat implementations of radix sort■

# Comparison of Sort Algorithms

# Lessons

- Sort is important—it is one of the commonest high level operations■
- Merge sort and quick sort are the most commonly used sort■
- There are sorts that have a better time complexity than quicksort■
- In practice it is difficult to beat quicksort■
