

## Lesson 18: Know Your Graph Algorithms

Weighted graph algorithms, Minimum spanning tree, Prim, Kruskal, shortest path, Dijkstra

BIOM2005

Further Mathematics and Algorithms

1

## Graph Algorithms

- We consider a graph algorithm to be **efficient** if it can solve a graph problem in  $O(n^a)$  time for some fixed  $a$
- That is, an efficient algorithm runs in polynomial time
- A problem is **hard** if there is no known efficient algorithm
- This does **not** mean the best we can do is to look through all possible solutions—see later lectures
- In this lecture we are going to look at some efficient graph algorithms for weighted graphs

BIOM2005

Further Mathematics and Algorithms

3

## Greedy Strategy

- We consider two algorithms for solving the problem
  - ★ Prim's algorithm (discovered 1957)
  - ★ Kruskal's algorithm (discovered 1956)
- Both algorithms use a **greedy strategy**
- Generally greedy strategies are not guaranteed to give globally optimal solutions
- There exists a class of problems with a **matroid** structure where greedy algorithms lead to globally optimal solutions
- Minimum spanning trees, Huffman codes and shortest path problems are matroids

BIOM2005

Further Mathematics and Algorithms

5

## Prim's Algorithm

- Prim's algorithm grows a subtree greedily
- Start at an arbitrary node
- Add the shortest edge to a node not in the tree

BIOM2005

Further Mathematics and Algorithms

7

- Minimum Spanning Tree
- Prim's Algorithm
- Kruskal's Algorithm
- Union Find
- Shortest Path

BIOM2005

Further Mathematics and Algorithms

2

## Minimum spanning tree

- A minimal spanning tree is the shortest tree which spans the entire graph

BIOM2005

Further Mathematics and Algorithms

4

## Outline

- Minimum Spanning Tree
- Prim's Algorithm
- Kruskal's Algorithm
- Union Find
- Shortest Path

BIOM2005

Further Mathematics and Algorithms

6

## Pseudo Code

```

PRIM( $G = (\mathcal{V}, \mathcal{E}, w)$ ) {
  for  $i \leftarrow 1$  to  $|\mathcal{V}|$ 
     $d_i \leftarrow \infty$  // Minimum 'distance' to subtree
  endfor
   $\mathcal{E}_T \leftarrow \emptyset$  // Set of edges in subtree
  PQ.initialise() // initialise an empty priority queue
   $node \leftarrow v_1$  // where  $v_1 \in \mathcal{V}$  is arbitrary
  for  $i \leftarrow 1$  to  $|\mathcal{V}| - 1$ 
     $d_{node} \leftarrow 0$ 
    for  $k \in \{v \in \mathcal{V} | (node, v) \in \mathcal{E}\}$  //  $k$  is a neighbours of node
      if ( $w_{node,k} < d_k$ )
         $d_k \leftarrow w_{node,k}$ 
        PQ.add( $(d_k, (node, k))$ )
      endif
    endfor
    do
      ( $a_{node}, next\_node$ )  $\leftarrow$  PQ.getMin()
    until ( $d_{next\_node} > 0$ )
     $\mathcal{E}_T \leftarrow \mathcal{E}_T \cup \{(a_{node}, next\_node)\}$ 
     $node \leftarrow next\_node$ 
  endfor
  return  $\mathcal{E}_T$ 
}

```

BIOM2005

Further Mathematics and Algorithms

8

## Prim's Algorithm in Detail

BIOM2005

Further Mathematics and Algorithms

9

## Proof by induction

- We want to show that each subtree,  $T_i$ , for  $i = 1, 2, \dots, n$  is part of (a subgraph) of some minimum spanning tree
- In the base case,  $T_1$  consists of a tree with no edges, but this has to be part of the minimum spanning tree
- To prove the inductive case we assume that  $T_i$  is part of the minimum spanning tree
- We want to prove that  $T_{i+1}$  formed by adding the shortest edge is also part of the minimum spanning tree
- We perform the proof by contradiction—we assume that this added edge isn't part of the minimum spanning tree

BIOM2005

Further Mathematics and Algorithms

11

## Loop Counting

```

PRIM( $G = (\mathcal{V}, \mathcal{E}, w)$ ) {
  for  $i \leftarrow 0$  to  $|\mathcal{V}|$ 
     $d_i \leftarrow \infty$ 
  endfor
   $\mathcal{E}_T \leftarrow \emptyset$ 
  PQ.initialise()
  node  $\leftarrow v_1$ 
  for  $i \leftarrow 1$  to  $|\mathcal{V}| - 1$  // loop 1  $O(|\mathcal{V}|)$ 
     $d_{\text{node}} \leftarrow 0$ 
    for  $k \in \{v \in \mathcal{V} | (node, v) \in \mathcal{E}\}$  // inner loop  $O(|\mathcal{E}|/|\mathcal{V}|)$ 
      if ( $w_{\text{node},k} < d_k$ )
         $d_k \leftarrow w_{\text{node},k}$ 
        PQ.add( $(d_k, (node, k))$ ) //  $O(\log(|\mathcal{E}|))$ 
      endif
    endfor
    do
      ( $a_{\text{node}}, \text{next\_node}$ )  $\leftarrow$  PQ.getMin()
    until ( $d_{\text{next\_node}} > 0$ )
     $\mathcal{E}_T \leftarrow \mathcal{E}_T \cup \{(node, \text{next\_node})\}$ 
    node  $\leftarrow$  next_node
  endfor
  return  $\mathcal{E}_T$ 
}

```

BIOM2005

Further Mathematics and Algorithms

13

## Outline

- Minimum Spanning Tree
- Prim's Algorithm
- Kruskal's Algorithm
- Union Find
- Shortest Path

BIOM2005

Further Mathematics and Algorithms

15

## Why Does This Work?

- Clearly Prim's algorithm produces a spanning tree
  - It is a tree because we always choose an edge to a node not in the tree
  - It is a spanning tree because it has  $|\mathcal{V}| - 1$  edges
- Why is this a minimum spanning tree?
- Once again we look for a proof by induction

BIOM2005

Further Mathematics and Algorithms

10

## Contrariwise

BIOM2005

Further Mathematics and Algorithms

12

## Run Time

- The worst time is

$$O(|\mathcal{V}|) \times O\left(\frac{|\mathcal{E}|}{|\mathcal{V}|}\right) \times O(\log(|\mathcal{E}|)) = O(|\mathcal{E}| \log(|\mathcal{E}|))$$

- Note that  $|\mathcal{E}| < |\mathcal{V}|^2$
- Thus,  $\log(|\mathcal{E}|) < 2 \log(|\mathcal{V}|) = O(\log(|\mathcal{V}|))$
- Thus the worst case time complexity is  $|\mathcal{E}| \log(|\mathcal{V}|)$

BIOM2005

Further Mathematics and Algorithms

14

## Kruskal's Algorithm

- Kruskal's algorithm works by choosing the shortest edges which don't form a loop

BIOM2005

Further Mathematics and Algorithms

16

```

KRUSKAL( $G = (\mathcal{V}, \mathcal{E}, w)$ )
{
    PQ.initialise()
    for edge  $\in |\mathcal{E}|$ 
        PQ.add(  $(w_{edge}, edge)$  )
    endfor

     $\mathcal{E}_T \leftarrow \emptyset$ 
    noEdgesAccepted  $\leftarrow 0$ 

    while (noEdgesAccepted <  $|\mathcal{V}| - 1$ )
        edge  $\leftarrow$  PQ.getMin()
        if  $\mathcal{E}_T \cup \{edge\}$  is acyclic
             $\mathcal{E}_T \leftarrow \mathcal{E}_T \cup \{edge\}$ 
            noEdgesAccepted  $\leftarrow$  noEdgesAccepted + 1
        endif
    endwhile

    return  $\mathcal{E}_T$ 
}

```

## Cycling

- For a path to be a cycle the edge has to join two nodes representing the same subtree
- To compute this we need to quickly **find** which subtree a node has been assigned to
- Initially all nodes are assigned to a separate subtree
- When two subtrees are combined by an edge we have to perform the **union** of the two subtrees
- This is a tricky but standard operation known as **union-find**

## Union-Find

- In the union-find algorithm we have a set of objects  $x \in \mathcal{S}$  which are to be grouped into subsets  $\mathcal{S}_1, \mathcal{S}_2, \dots$
- Initially each object is in its individual subset (no relationships)
- We want to make the **union** of two subsets (add relationship between elements)
- We also want to **find** the subset given an element
- This is a common problem for which we will write a class `DisjointSets` to perform fast unions and finds

## The Union-Find Dilemma

- A natural algorithm to perform finds is to maintain an array returning a subset label for each element—this makes **find** fast
- However, every time we combine two subset we have to change all the labels in this array (taking  $O(n)$  operations)
- If we are unlucky the cost of performing  $n$  unions is  $\Theta(n^2)$
- If we ensure that we relabel the smaller subset then the time complexity is  $\Theta(n \log(n))$
- Fast **finds** seems to give slow(ish) **unions**
- What about the other way around?

- Kruskal's algorithm looks much simpler than Prim's
- The sorting takes most of the time, thus Prim's algorithms is  $O(|\mathcal{E}| \log(|\mathcal{E}|)) = O(|\mathcal{E}| \log(|\mathcal{V}|))$
- We can sort the edges however we want—we could use quick sort rather than heap sort using a priority queue
- But we haven't specified how we determine if the added edge would produce a cycle

## Outline

- Minimum Spanning Tree
- Prim's Algorithm
- Kruskal's Algorithm
- Union Find**
- Shortest Path

## DisjointSets

- We want to create a class
- ```

class DisjointSets
{
    DisjointSets(int numElements) { /* Constructor */}
    int find(int x) { /* Find root */}
    void union(int root1, int root2) { /* Union */}

private:
    int[] s;
}

```
- Where `find(x)` returns a unique identifier for the subset which element  $x$  belongs to
  - The array `s` contains labelling information to implement `find(x)`

## Fast Union

- To achieve fast unions we can represent our disjoint sets as a forest (many disjoint trees)
- Every time we perform a union we make one of the trees point to the head of the other tree
- The cost of **find** depends on the depth of the tree
- To make unions efficient we make the shallow tree a subtree of the deeper tree

## Putting it Together

find(6)=7

## Path Compression

- To speed up `find` we relabel all nodes we visit during `find` by the root label

```
public int DisjointSets::find(int index)
{
    if (s[index]<0)
        return index;
    else
        return s[index] = find(s[index]);
}
```

## Time Complexity of Union-Find

- If we perform  $M$  finds and  $N$  unions then the time complexity is  $O(M \log_2^*(N))$ ■
- Where  $\log_2^*(N)$  is the number of times you need to apply the logarithm function before you get a number less than 1■
- In practice  $\log_2^*(N) \leq 5$  for all conceivable  $N$ ■

$$\log_2(\log_2(\log_2(\log_2(\log_2(\log_2(106699))))))=0.36895$$

- The proof of this time complexity is rather involved

### Shortest path

- We can efficiently compute the shortest path from one vertex to any other vertex
- This defines a spanning tree, but where the optimisation criteria is that we choose the vertex that are closest to the *source*
- To find this spanning tree we use Dijkstra's algorithm where we successively add the nearest node to the source which is connected to the subtree built so far
- This is very close to Prim's algorithm and has the same complexity

## Smart Union

```
DisjointSets::DisjointSets(int numElements)
{
    s = new int[numElements];
    for(int i=0; i<s.length; i++)
        s[i] = -1; // roots are negative number
}

void DisjointSets::union(int root1, int root2)
{
    if (s[root2]<s[root1]) { // root2 is deeper
        s[root1] = root2; // make root2 the root
    } else {
        if (s[root1]==s[root2]) // update height if same
            s[root1]--; // make root1 new root
        s[root2] = root1;
    }
}
```

## Mazes

- Union-Find is a data structure which can occur in very different applications
- One application is building a maze
- Start from a complete lattice
- Remove a randomly chosen edge if it connects two unconnected regions
- Stop when the start and end cell are connected
- Or better after all cells are connected

|    |    |    |    |    |
|----|----|----|----|----|
| 0  | 1  | 2  | 3  | 4  |
| 5  | 6  | 7  | 8  | 9  |
| 10 | 11 | 12 | 13 | 14 |
| 15 | 16 | 17 | 18 | 19 |
| 20 | 21 | 22 | 23 | 24 |
| 25 | 26 | 27 | 28 | 29 |
| 30 | 31 | 32 | 33 | 34 |
| 35 | 36 | 37 | 38 | 39 |

## Outline

1. Minimum Spanning Tree
2. Prim's Algorithm
3. Kruskal's Algorithm
4. Union Find
5. **Shortest Path**

## Dijkstra's Algorithm

## Pseudo Code

```
DIJKSTRA( $G = (\mathcal{V}, \mathcal{E}, w)$ , source){
  for  $i \leftarrow 0$  to  $|\mathcal{V}|$ 
     $d_i \leftarrow \infty$       \ \ Minimum 'distance' to source
  endfor
   $\mathcal{E}_T \leftarrow \emptyset$     \ \ Set of edges in subtree
  PQ.initialise() \ \ initialise an empty priority queue
  node  $\leftarrow$  source
   $d_{\text{node}} \leftarrow 0$ 
  for  $i \leftarrow 1$  to  $|\mathcal{V}| - 1$ 
    for  $k \in \{v \in \mathcal{V} | (node, v) \in \mathcal{E}\}$ 
      if (  $w_{node,k} + d_{node} < d_k$  )
         $d_k \leftarrow w_{node,k} + d_{node}$ 
        PQ.add( ( $d_k$ , (node, k)) )
      endif
    endfor
    do
      ( $a_{\text{node}}$ , next_node)  $\leftarrow$  PQ.getMin()
      while next_node not in subtree
         $\mathcal{E}_T \leftarrow \mathcal{E}_T \cup \{(a_{\text{node}}, \text{next\_node})\}$ 
        node  $\leftarrow$  next_node
      endwhile
    endfor
  return  $\mathcal{E}_T$ 
}
```

BIOM2005

Further Mathematics and Algorithms

33

## Dijkstra Details

- Dijkstra is very similar to Prim's (it differs in the distances that are used)
- It has the same time complexity
- It can be viewed as using a greedy strategy
- It can also be viewed as using the dynamic programming strategy (see lecture 22)

BIOM2005

Further Mathematics and Algorithms

35

## Compare to Prim's Algorithm

```
PRIM( $G = (\mathcal{V}, \mathcal{E}, w)$ ) {
  for  $i \leftarrow 1$  to  $|\mathcal{V}|$ 
     $d_i \leftarrow \infty$       \ \ Minimum 'distance' to subtree
  endfor
   $\mathcal{E}_T \leftarrow \emptyset$     \ \ Set of edges in subtree
  PQ.initialise() \ \ initialise an empty priority queue
  node  $\leftarrow v_1$       \ \ where  $v_1 \in \mathcal{V}$  is arbitrary
  for  $i \leftarrow 1$  to  $|\mathcal{V}| - 1$ 
     $d_{\text{node}} \leftarrow 0$ 
    for  $k \in \{v \in \mathcal{V} | (node, v) \in \mathcal{E}\}$ 
      if (  $w_{node,k} < d_k$  )
         $d_k \leftarrow w_{node,k}$ 
        PQ.add( ( $d_k$ , (node, k)) )
      endif
    endfor
    do
      ( $a_{\text{node}}$ , next_node)  $\leftarrow$  PQ.getMin()
      until ( $d_{\text{next\_node}} > 0$ )
       $\mathcal{E}_T \leftarrow \mathcal{E}_T \cup \{(a_{\text{node}}, \text{next\_node})\}$ 
      node  $\leftarrow$  next_node
    endwhile
  endfor
  return  $\mathcal{E}_T$ 
}
```

BIOM2005

Further Mathematics and Algorithms

34

## Lessons

- There are many efficient (i.e. polynomial  $O(n^a)$ ) graph algorithms
- Some of the most efficient ones are based on the Greedy strategy
- These are easily implemented using priority queues
- Minimum spanning trees are useful because they are easy to compute
- Dijkstra's algorithm is one of the classics
