

# Algorithms and Analysis

## Lesson 21: *Know Your Graph Algorithms*

*Weighted graph algorithms, Minimum spanning tree, Prim, Kruskal, shortest path, Dijkstra*

# Outline

1. **Minimum Spanning Tree**
2. Prim's Algorithm
3. Kruskal's Algorithm
4. Shortest Path

# Graph Algorithms

- We consider a graph algorithm to be **efficient** if it can solve a graph problem in  $O(n^a)$  time for some fixed  $a$
- That is, an efficient algorithm runs in polynomial time
- A problem is **hard** if there is no known efficient algorithm
- This does **not** mean the best we can do is to look through all possible solutions—see later lectures
- In this lecture we are going to look at some efficient graph algorithms for weighted graphs

# Graph Algorithms

- In this lecture we are going to look at some efficient graph algorithms for weighted graphs

# Minimum spanning tree

- A minimal spanning tree is the shortest tree which spans the entire graph

# Minimum spanning tree

- A minimal spanning tree is the shortest tree which spans the entire graph

# Greedy Strategy

- We consider two algorithms for solving the problem
  - ★ Prim's algorithm (discovered 1957)
  - ★ Kruskal's algorithm (discovered 1956)
- Both algorithms use a **greedy strategy**
- Generally greedy strategies are not guaranteed to give globally optimal solutions
- There exists a class of problems with a **matroid** structure where greedy algorithms lead to globally optimal solutions
- Minimum spanning trees, Huffman codes and shortest path problems are matroids

# Outline

1. Minimum Spanning Tree
2. **Prim's Algorithm**
3. Kruskal's Algorithm
4. Shortest Path

# Prim's Algorithm

- Prim's algorithm grows a subtree greedily
- Start at an arbitrary node
- Add the shortest edge to a node not in the tree

# Prim's Algorithm

- Prim's algorithm grows a subtree greedily
- Start at an arbitrary node
- Add the shortest edge to a node not in the tree

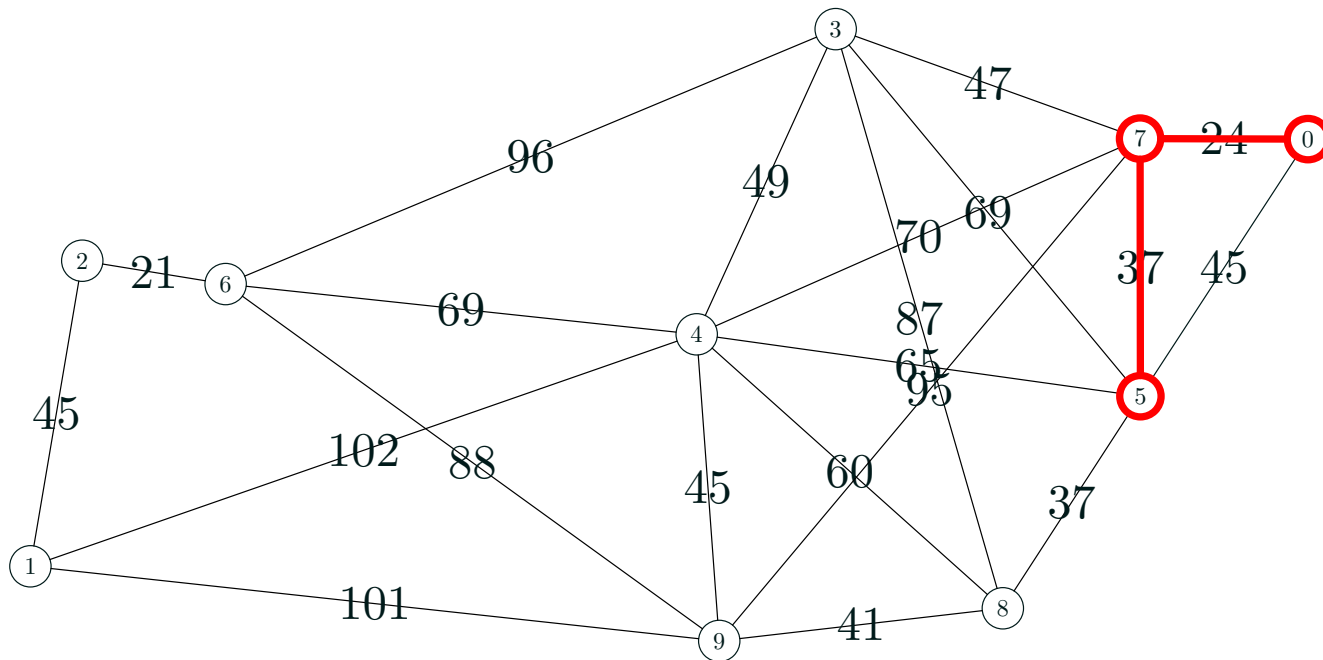

# Prim's Algorithm

- Prim's algorithm grows a subtree greedily
- Start at an arbitrary node
- Add the shortest edge to a node not in the tree

# Prim's Algorithm

- Prim's algorithm grows a subtree greedily
- Start at an arbitrary node
- Add the shortest edge to a node not in the tree

# Prim's Algorithm

- Prim's algorithm grows a subtree greedily
- Start at an arbitrary node
- Add the shortest edge to a node not in the tree

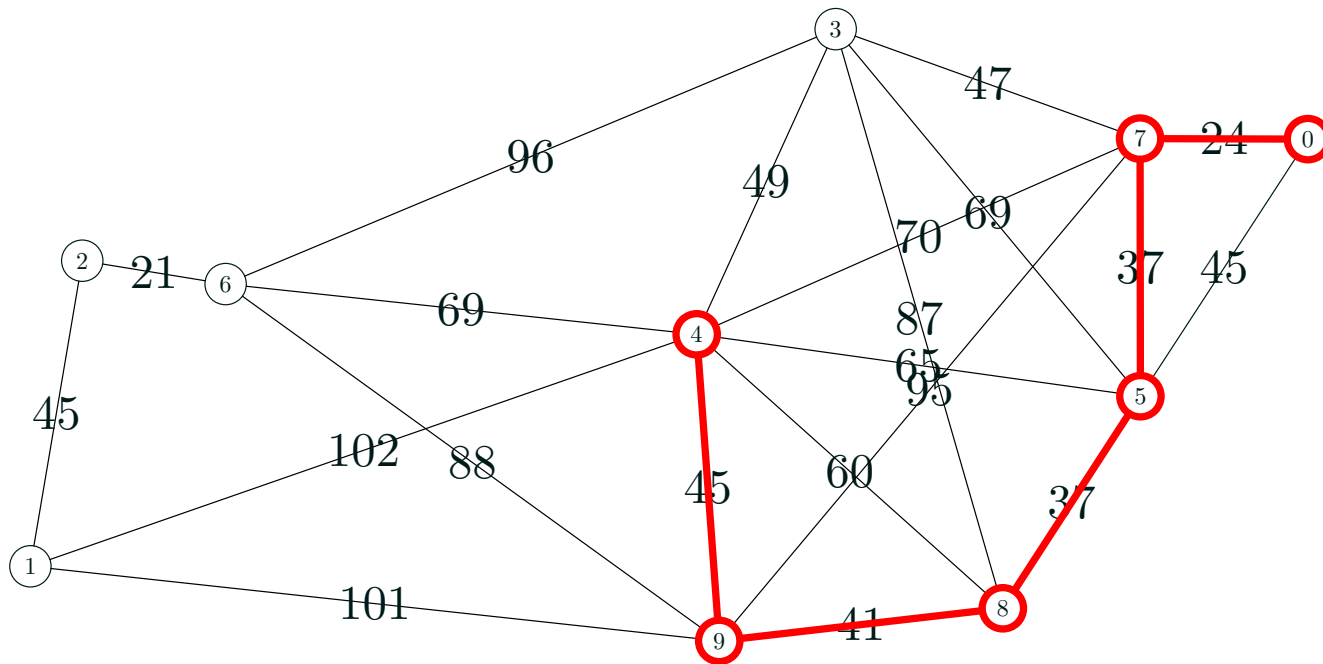

# Prim's Algorithm

# Why Does This Work?

- Clearly Prim's algorithm produces a spanning tree
  - ★ It is a tree because we always choose an edge to a node not in the tree
  - ★ It is a spanning tree because it has  $|\mathcal{V}| - 1$  edges
- Why is this a minimum spanning tree?
- Once again we look for a proof by induction

# Why Does This Work?

# Proof by induction

- We want to show that each subtree,  $T_i$ , for  $i = 1, 2, \dots, n$  is part of (a subgraph) of some minimum spanning tree
- In the base case,  $T_1$  consists of a tree with no edges, but this has to be part of the minimum spanning tree
- To prove the inductive case we assume that  $T_i$  is part of the minimum spanning tree
- We want to prove that  $T_{i+1}$  formed by adding the shortest edge is also part of the minimum spanning tree
- We perform the proof by contradiction—we assume that this added edge isn't part of the minimum spanning tree

# Proof by induction

# Cycling

- For a path to be a cycle the edge has to join two nodes representing the same subtree
- To compute this we need to quickly **find** which subtree a node has been assigned to
- Initially all nodes are assigned to a separate subtree
- When two subtrees are combined by an edge we have to perform the **union** of the two subtrees
- But that is precisely the **union-find** algorithm we covered in lecture 13

# Outline

1. Minimum Spanning Tree
2. Prim's Algorithm
3. Kruskal's Algorithm
4. **Shortest Path**

# Shortest path

- We can efficiently compute the shortest path from one vertex to any other vertex
- This defines a spanning tree, but where the optimisation criteria is that we choose the vertex that are closest to the *source*
- To find this spanning tree we use Dijkstra's algorithm where we successively add the nearest node to the source which is connected to the subtree built so far
- This is very close to Prim's algorithm and has the same complexity

# Shortest path

# Dijkstra Details

- Dijkstra is very similar to Prim's (it differs in the distances that are used)
- It has the same time complexity
- It can be viewed as using a greedy strategy
- It can also be viewed as using the dynamic programming strategy (see lecture 22)

# Lessons

- There are many efficient (i.e. polynomial  $O(n^a)$ ) graph algorithms
- Some of the most efficient ones are based on the Greedy strategy
- These are easily implemented using priority queues
- Minimum spanning trees are useful because they are easy to compute
- Dijkstra's algorithm is one of the classics
