

### Lesson 7: Iterate

Array iteration, iterators

1. **Iterators**
2. The C++ Iterator Pattern
3. Linked-List Iterators
4. Generic Programming

## Iterators

- One common task you want to do on a collection of objects is to iterate through each component
- If we have a standardised method for all collections then it is much easier to remember what to do
- But we can also write code that works for any collection that follows this pattern
- This pattern is known as the **iterator pattern**
- The pattern was first developed in C++, but is commonly used in many other languages

## Iterating Over C Arrays

- In C we would typically use a for-loop to iterate over an array

```
int n = 10;                                // size of array
int* begin = malloc(n*sizeof(10));           // malloc returns beginning of array
int* end = begin + n;                      // address past end of array

int sum = 0;
for(int* pt = begin; pt != end; pt++) {
    sum += *pt;                            // need to dereference pointer
}
```

- Ugly but efficient

# Outline

1. Iterators
2. The C++ Iterator Pattern
3. Linked-List Iterators
4. Generic Programming

# C++ Iterator Pattern

- The C++ iterator pattern says for every `container<T>` we create a nested class called  
`container::iterator`  
which acts as a pointer (for arrays this could just be a pointer to the array)
- The class should implement
  - ★ a dereferencing operator `T operator*()`
  - ★ an increment operator `operator++()`
  - ★ a not equal function  
`bool operator!=(const ITER&, const ITER&)`  
where `ITER` is `container::iterator`

## A Beginning and an Ending

- In addition the container should have two methods
  - ★ `begin()`
  - ★ `end()`that return iterators representing the first element and an iterator representing one position past the last element
- Wow! That seems awfully complicated
- Don't panic! We can hack this

## Minimal Iterator

```
template <typename>
class Container<T> {
private:

    class iterator { // this is a nested class
public:
    iterator() {...} // constructor
    iterator operator++() {...} // increment
    T& operator*() {...} // dereference
    friend bool operator!=(const iterator&, const iterator&){
        // code to determine inequality
    }
}

public:

    iterator begin() {...} // return begin iter
    iterator end() {...} // return end iter
}
```

- For array based containers such as vector we don't actually need to create an iterator class as we can just use the normal pointer

```
template <typename T>
class Array {
private:
    T *data;
    unsigned length;
    unsigned capacity;

public:
    ...
    typedef T* iterator;           // iterator is pseudonym for T
    iterator begin() {return data; }
    iterator end() {return data+length; }
};
```

- That's all we need!

## Outline

- Iterators
- The C++ Iterator Pattern
- Linked-List Iterators**
- Generic Programming

```
main() {

    Array<string> elements(4): {"earth", "water", "wind", "fire"};  
  

    for(Array::iterator it=elements.begin(); it!=elements.end(); ++it) {
        cout << *it << endl;
    }  
  

    for(auto it=elements.begin(); it!=elements.end(); ++it) {
        cout << *it << endl;
    }  
  

    for(string& element: elements) { // range-based loop
        cout << element << endl;
    }
}
```

## Linked-List Iterators

- Linked-lists are not array based!
- To use the iterator we need to implement the iterator class!
- The object instantiated from the class should represent the position we are in the linked list!

## Linked-List

```
template <typename T>
class MyList { // My linked list class
private:
    struct Node{ // A simple node nested class
        Node(T value, Node *node): value(value), next(node) {}
        T value;
        Node *next;
   };

    struct iterator { // An iterator class
        Node* entry; // Holds node pointer
        iterator(Node* pt): entry(pt) {} // constructor
        T& operator*() {return entry->value;} // dereferencing
        const T& operator*() const {return entry->value;}
        iterator operator++() { // next entry
            entry = entry->next;
            return entry;
        }
        bool operator==(const iterator& other) const {
            return entry == other.entry;
        }
    };
};
```

## Linked-List

```
template <typename T>
class MyList {
private:
    struct Node{...}

    struct iterator {...};

    Node* head; // head of linked list
    unsigned no_elements;

public:
    MyList(): head(nullptr), no_elements(0) {}

    void add(T value) {...}

    iterator begin() {return iterator(head);}
    iterator end() {return nullptr;}
}
```

## Increment Operators

- C++ has a pre-increment opeator `++a` and a post-increment operator `a++`
- The pre-increment operator increments `a` and returns the incremented version, e.g.  
`T& operator++() {++count; return *this;} // defines ++a`
- The post-increment operator copies `a` increments it and returns the copy, e.g.  
`T operator++(int) {T b=a; ++count; return b;} // defines a++`
- The `int` argument is not used, but tells the compiler which increment is which
- We might want to implement `it++`

## Const Iterators

- C++ uses the compiler to test whether functions change their argument or not

```
func1(Class obj) // obj is copied so will only modify copy
func2(Class& obj) // passed by reference, might change obj
func3(const Class& Obj) // will not change obj
```

- `func3` will only call methods of `Obj` that are `const`

```
class Class {
    void method() const; // won't change the object
    void change(); // might change the object
}
```

- We want to declare a `const` iterator so need to define

```
const T& operator*() const // const dereferencing operator
```

## Bidirectional Iterators

- For the linked list we have implemented a **forward iterator**
  - This is the only iterator possible for a singly linked list
  - For a doubly linked list we can implement a **bidirectional iterator**
  - This requires us to implement the decrement operators
- ```
T& operator--(); // implements —obj
T operator--(int); //implements obj—
```
- 
- There also exist **random-access iterators** that implements methods including
- ```
T& operator[int i] // returns i'th element
operator+=[int i] // move forward i places
```

## Outline

- Iterators
- The C++ Iterator Pattern
- Linked-List Iterators
- Generic Programming

## Range-Based For Loop

- C++ allows you to iterate over collections elegantly

```
Collection<string> collection;

for (string& element: collection) {
    print(element); // or whatever function you want
}
```

- This is syntactic sugar! The compiler just replaces this with

```
for(auto& it=collection.begin(); it!=collection.end(); ++it) {
    print(*it);
}
```

- This works for any class that has an iterator

- auto** just works out the correct type

- By being pretty it reduces bugs in code

Algorithms and Analysis

19

## Generic Algorithms

- Iterators allow us to write generic functions

- E.g. summing elements

```
template <typename Iter, typename T>
T accum(Iter it, Iter end, T init) {
    for(; it != end; ++it)
        init += *it;
    return init;
}
```

- This will sum many collections

```
int array[20];
vector<double> v[5];
set<int> s;

cout << "array_sum=" << accum(&array[0], &array[20], 0) << endl;
cout << "vector_sum=" << accum(v.begin(), v.end(), 0.0) << endl;
cout << "set_sum=" << accum(s.begin(), s.end(), 0) << endl;
```
