# **Further Mathematics and Algorithms**

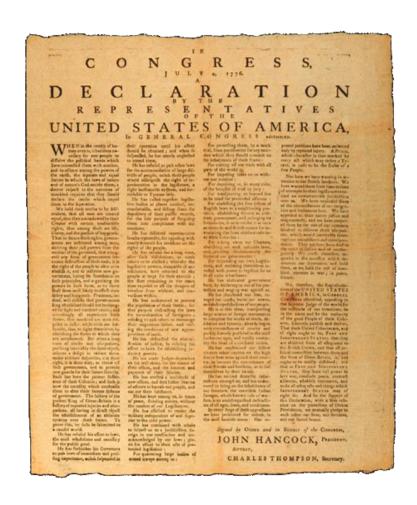

**Lesson 3:** Declare your intentions (not your actions)

ADTs, stacks, queues, priority queues, sets, maps

### **Outline**

- Abstract Data Types (ADTs)
- 2. Stacks
- 3. Queues and Priority Queues
- 4. Lists, Sets and Maps
- 5. Putting it Together

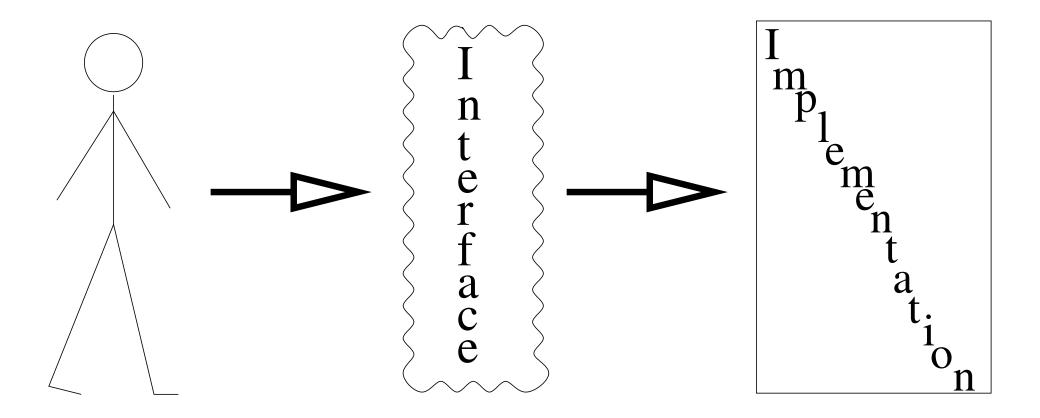

# **Object Oriented Programming**

- OO-programming allows you to build large systems reliably
- In the OO-methodology you separate the interface from the implementation
- The interface is the public methods (functions) of a class
- The implementation is hidden (encapsulated) and may be changed without affecting how the class is used.
- There exist other ways of programming, but C++ is designed to support the OO-methodology

  for building systems it is brilliant

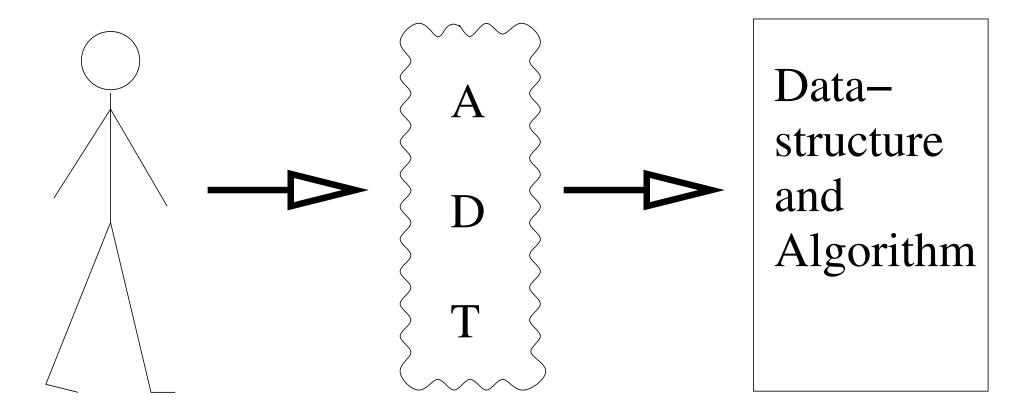

# **Object-Oriented Classes**

### **Abstract Data Types**

- With data structures there are some traditional interfaces called
   Abstract Data Types or ADTs
- These are implementation free data structures
- They are mathematical abstractions of the data structure
- Their purpose is to allow you to declare you intentions
- You are entering into an agreement that you only intend to use the underlying data structure in the way specified by the interface.

### **ADTs**

# Say it with an ADT

- Common ADTs include stacks, queues, priority queues, sets, multisets and maps
- There are many possible implementations of these ADTs (some far from obvious)
- Each ADT has a limited set of methods associated with it
- They are an abstraction away from the implementation
- By declaring your intentions you are making your code easier to understand and maintain

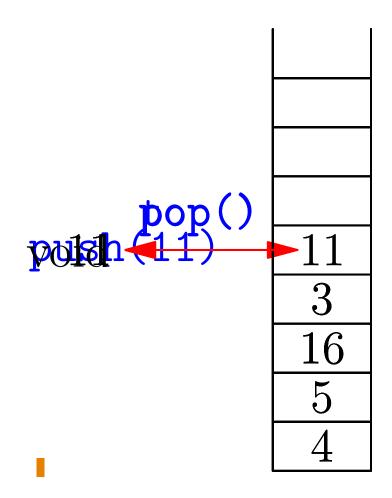

#### **Outline**

- Abstract Data Types (ADTs)
- 2. Stacks
- 3. Queues and Priority Queues
- 4. Lists, Sets and Maps
- 5. Putting it Together

#### **Stacks**

- Last In First Out (LIFO) memory
- Standard functions
  - ★ push (item)
  - ★ T top()
  - ★ T pop() except in C++ pop()
    doesn't return the top of the stack
  - ★ boolean empty()
- Implemented using an array (or a linked-list)

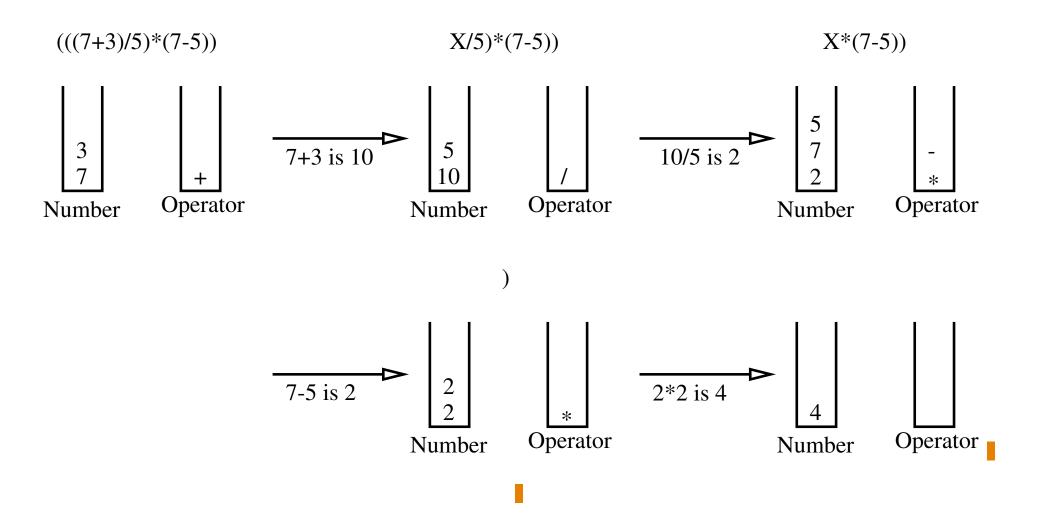

# Why Use a Stack?

- Stacks reduces the access to memory—no longer random access
- Seems counter intuitive to reduce what you can do!
- Gives you a very simple interface
- Prevents another programmer from using memory in a way that will break existing code
- Sufficient for large number of algorithms

#### **Uses of Stacks**

- Reversing an array
- Parsing expression for compilers
  - ★ balancing parentheses
  - ★ matching XML tags
  - ★ evaluating arithmetic expression
- Clustering algorithm

### **Evaluating Arithmetic Expressions**

#### **Outline**

- Abstract Data Types (ADTs)
- 2. Stacks
- 3. Queues and Priority Queues
- 4. Lists, Sets and Maps
- 5. Putting it Together

### Queues

- First-in-first-out (FIFO) memory model
- enqueue (elem)
- peek()
- dequeue()
- C++ has a double ended queue (deque) with push\_front(), push\_back(), etc.

F E D C B

### **Uses of Queues**

- Queues are heavily used in multi-threaded applications (e.g. operating systems)
- Multi-threaded applications need to minimise waiting and ensure the integrity of the data structure (for instance when an exception is thrown)
- Because of this they are more complicated than most data structures
- They can be implemented using linked-lists or circular arrays

### **Priority Queues**

- Queue with priorities
- insert (elem, priority) (in C++ push())
- findMin() (in C++ top())
- deleteMin() (in C++ pop())

# **Uses of Priority Queues**

- Queues with priorities (e.g. which threads should run)
- Real time simulation
- Often used in "greedy algorithms"
  - \* Huffman encoding
  - ★ Prim's minimum spanning tree algorithm

# Implementation of Priority Queue

- Could be implemented using a binary tree or linked list
- Most efficient implementation uses a heap!
- A heap is a binary tree implemented using an array

#### **Outline**

- Abstract Data Types (ADTs)
- 2. Stacks
- 3. Queues and Priority Queues
- 4. Lists, Sets and Maps
- 5. Putting it Together

#### Lists

- In C++ the standard list is known as vector<T>I
- That is, it is a collection where the order in which you put items into the list counts
- You can have repetitions of elements
- It has random access, e.g. ▽[i]
- You can push\_back(i), insert, erase, etc.
- C++ has a linked list class List<T>■

#### Sets

- Models mathematical sets
- Container with no ordering or repetitions
- Methods include insert, find, size, erase
- Provides fast search (find)
- This is the class to use when you have to rapidly find whether an object is in the set or not—don't use a list like vector<T>!

#### **Iterators**

- Wish to act on all members of the set
- Performed using an iterator
- Iterators are used by many collections
- In C++ iterators follow the pointer convention

```
set<string> words;

words.insert("hello");
words.insert("world");

for(auto iter = words.begin(); iter != words.end(); ++iter) {
  cout << *iter << endl;
}</pre>
```

# Implementation of Sets

- Sets are very important and there are many implementations depending on their usage
- Two common implementations of sets are
  - \* hash tables: unordered\_set<T>
  - ★ binary trees: set<T>
- Which is most efficient depends on the application
- Binary trees allow you to iterate in order (iterating over a hash table will give you outputs in random order)
- multiset<T> are sets with repetition

### Maps

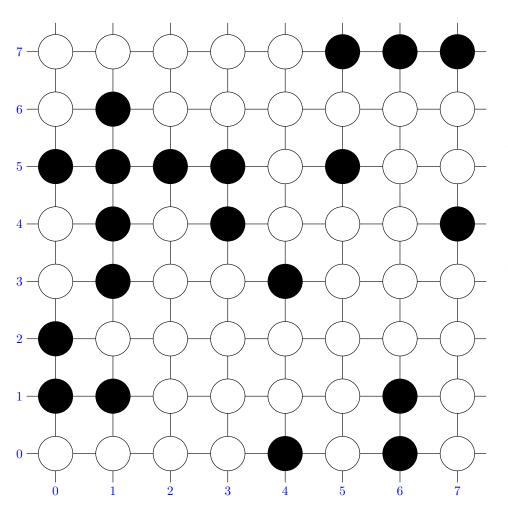

- A map provides a content addressable memory for pairs keyword:
   data
- It provides fast access to the data through the keyword
- Implement as tree or hash table
- Multimaps allows different data to be stored with the same keyword

#### **Outline**

- Abstract Data Types (ADTs)
- 2. Stacks
- 3. Queues and Priority Queues
- 4. Lists, Sets and Maps
- 5. Putting it Together

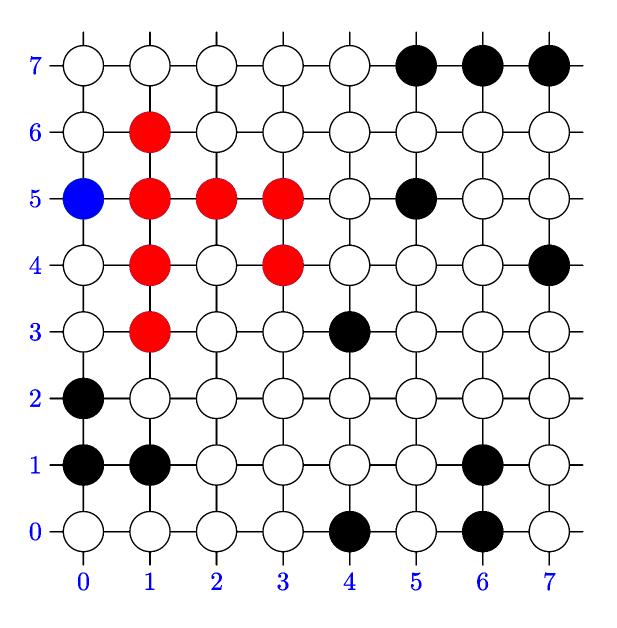

#### **Connected Nodes**

- A frequent problem is to find clusters of connected cells
- Applications in computer vision, computer go, graph connectedness, . . .

#### **Connected Nodes**

steart No (10, 
$$\bullet$$
)  $(2,5)$ 

uncheckedNodes =

clusterNodes = 
$$\{\}(2,5), \{(1,5), (3,5), \{(3,4), \{(0,5), (1,4), (1,6), \{(1,3)\}\}$$

### **Connected Node Algorithm**

```
set < Node > findCluster(Node startNode, Graph graph)
  stack<Node> uncheckedNodes = new Stack<Node>();
  set < Node > clusterNodes = new HashSet < Node > ();
 uncheckedNodes.push(startNode);
  clusterNodes.add(startNode);
 while (!uncheckedNodes.empty()) {
   Node next = uncheckedNodes.top(); uncheckedNodes.pop();
   vector<Node> neighbours = graph.getNeighbours(next);
    for (Node neigh: neighbours) {
      if (graph.isOccupied(neigh) && !clusterNodes.contains(neigh) ) {
        uncheckedNodes.push (neigh);
        clusterNodes.insert(neigh);
 return clusterNodes;
```

#### Lessons

- Abstract Data Types (ADT) are interfaces to data
- Their purpose is to allow the programmer to declare their intentions
- They often have different implementations with different properties
- The most efficient implementation is not always obvious—we will see many of these implementations as we go through this course
- You need to know the common ADTs (e.g. Stack, Queue, List, Set, Map) and how and when to use them
