BIOM2005 Further Mathematics and Algorithms 3 BIOM2005 Further Mathematics and Algorithms

Example Tour

Brute Force

- I wrote a program to solve TSP by enumerating every path and finding the shortest
- I checked that it worked on some problems with 10 cities!
- It takes just under half a second to solve this problem!
- I set the program running on a 100 city problem—How long will it take to finish?■

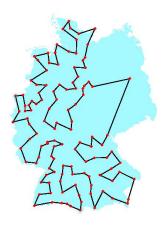

BIOM2005

Further Mathematics and Algorithms

BIOM2005

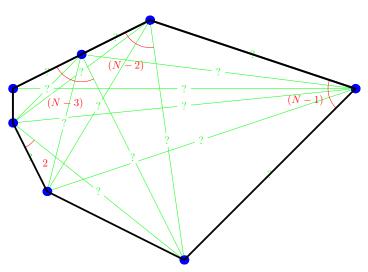

Further Mathematics and Algorithms

How Many Possible Tours Are There?

- For 100 cities how many possible tours are there?
- It doesn't matter where we start!
- Starting from Berlin there are 99 cites we can try next

Counting Tours

Number of tours = $(N-1) \times (N-2) \times (N-3) \times \cdots \times 2 \times 1 = (N-1)!$

BIOM2005

How Long Does It Take?

How Big is 99 Factorial?

• The direction we go in is irrelevant

• Total number of tours is 99!/2

• Any more guesses how long it will take?

BIOM2005

Further Mathematics and Algorithms

How Long Does It Take?

 $\bullet \ \operatorname{For} \ N>1$

$$\left(\frac{N}{2}\right)^{N/2} < N! < N^N \mathbf{I}$$

- $99!/2 = 4.666 \times 10^{155}$
- How long does it take to search all possible tours?
 - \star We computed about $200\,000$ tours in half a second
 - $\star~3.15 \times 10^7 \mathrm{sec} = 1~\mathrm{year}$
 - \star Age of Universe ≈ 15 billion years

•
$$99! = 99 \cdot 98 \cdot 97 \cdots 2 \cdot 1 = ?$$

• Upper bound

$$99! = 99 \cdot 98 \cdot 97 \cdots 2 \cdot 1$$

$$99! < 99 \cdot 99 \cdot 99 \cdots 99 \cdot 99 = 99^{99}$$

Lower bound

99! =
$$99 \cdot 98 \cdot 97 \cdots 50 \cdot 49 \cdots 2 \cdot 1$$

99! > $50 \cdot 50 \cdot 50 \cdots 50 \cdot 1 \cdots 1 \cdot 1 = 50^{50}$

BIOM2005

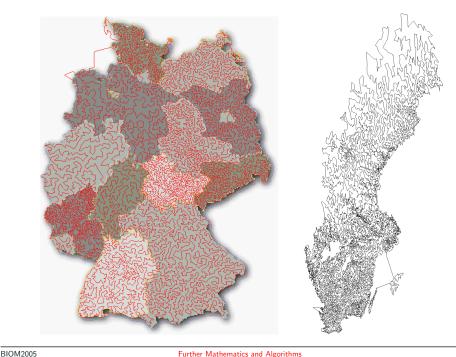

Further Mathematics and Algorithms

Answer

- 2.72×10^{132} ages of the universe!
- Incidental

99!/2 = 46663107721972076340849619428133350 24535798413219081073429648194760879 99966149578044707319880782591431268 48960413611879125592605458432000000 0000000000000000000

Record TSP Solved—15 112 and 24 978 Cities

• Even relatively small problems can take you an astronomical time to solve using simple algorithms!

Lessons

- As a professional programmer you need to have an estimate for how long an algorithm takes—otherwise you can look silly
- For the 100 city problem, if
 - \star I had 10^{87} cores, one for every particle in the Universe
 - \star I could compute a tour distance in 3×10^{-24} seconds, the time it takes light to cross a proton.
 - \star It would still take $10^{39}\times$ the age of the universe
- Smart algorithms can make a much larger difference than fast computers!

In Case You're Curious

- Number of tours: $15111!/2 = 7.3 \times 10^{56592}$
- \bullet Current record $24\,978$ cities with 1.9×10^{98992} tours
- The algorithm for finding the optimum path does not look at every possible path
- If your interested look for the TSP homepage on the web http://www.math.uwaterloo.ca/tsp/

BIOM2005

Further Mathematics and Algorithms

Outline

- 1. TSP
- 2. Sorting
- 3. Big O

Sort

- Comparison between common sort algorithms
 - ★ Insertion sort—an easy algorithm to code
 - ★ Shell sort—invented in 1959 by Donald Shell
 - ★ Quick sort—invented in 1961 by Tony Hoare
- These take an array of numbers and returns a sorted array
- Sort is very commonly used algorithm so you care about how long it takes

BIOM2005 Further Mathematics and Algorithms

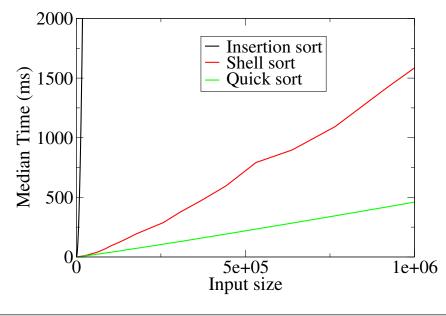

Lessons

- There is a right and wrong way to do easy problems
- You only really care when you are dealing with large inputs
- Good algorithms are difficult to come up with, but they exist
- We would like to quantify the performance of an algorithm

 —how much better is quick sort than insertion sort?

 ■

Empirical Run Times

BIOM2005 Further Mathematics and Algorithms

Outline

Further Mathematics and Algorithms

- 1. TSP
- 2. Sorting
- 3. **Big O**

Estimating Run Times

- We would like to estimate the run times of algorithms
- This depends on the hardware (how fast is your computer)
- We could count number of elementary operations but
 - ★ different machines have different elementary operations
 - ★ many algorithms use complex functions such as sqrt (matrix inversion using Cholesky decomposition) or sin and cos (FFT)
 - ★ would need to count memory accesses which you shouldn't need to think about
 - ★ code after compiling can be very different from code before compiling •

BIOM2005 Further Mathematics and Algorithms

Advantages of Big-Theta Notation

- Doesn't depend on what computer we are running
- Don't need to know how many elementary operations are required for a non-elementary operation
- Can estimate run times by measuring run time on a small problem
 - \star If I have a $\Theta(n^2)$ algorithm
 - \star It takes x seconds on an input of $100\,$
 - * It will take about $\frac{x \times n^2}{100^2}$ seconds on a problem of size n ($T(100) \approx c \, 100^2 = x$ therefore $c = x/100^2$ thus $T(n) = c \, n^2 = x \, n^2/100^2$)

Engineering Solution

- Compute the asymptotic leading functional behaviour
- Lets take that statement to pieces
- Suppose we have an algorithm that takes $4n^2 + 12n + 199$ operations (clock cycles)
 - \star asymptotic: what happens when n becomes very large
 - **Leading**: ignore the 12n+199 part as it is dominated by $4n^2$ (i.e. for large enough n we have $4n^2\gg 12n+199$)
 - \star functional behaviour: ignore the constant 4
- ullet We call this an order n^2 , or quadratic time, algorithm
- We can write this in 'Big-Theta' notation as $\Theta(n^2)$
- This notion of 'run time' is known as time complexity

BIOM2005

Further Mathematics and Algorithms

.

Counting Instructions

- Big-Theta run times are often easy to calculate
- a $\Theta(n)$ algorithm

```
// define stuff
for(int i=0; i<n; i++) {
   // do something
}
// clean up </pre>
```

• a $\Theta(n^2)$ algorithm

```
// define stuff
for(int i=0; i<n; i++) {
   // do something
   for (int j=0; j<n; j++) {
      // do other stuff
   }
}
// clean up</pre>
```

BIOM2005

Disadvantage with Big-Theta notation

- Can't compare algorithms with the same Big-Theta time complexity
- For small inputs Big-Theta time complexity can be misleading. E.g.
 - \star algorithm A takes $n^3 + 2n^2 + 5$ operations
 - \star algorithm B takes $20n^2 + 100$ operations
 - \star algorithm A is $\Theta(n^3)$ and algorithm B is $\Theta(n^2)$
 - \star algorithm A is faster than algorithm B for n < 18

but who cares?

• In some cases Big-Theta time complexity is hard to compute

BIOM2005

Further Mathematics and Algorithms

Further Mathematics and Algorithms

Bounds

- To avoid having to think really hard we define upper and lower bounds
- The upper bound we write using **big-O** notation
 - \star The above algorithm is an $O(n^2)$ algorithm
 - \star l.e. it runs in no more than order n^2 operations
- The lower bound we write using **big-Omega** notation
 - \star The above algorithm is a $\Omega(n)$ algorithm
 - \star l.e. it runs in no less than order n operations

Not So Sure

• Some algorithms are harder to compute

```
// define stuff
for (int i=0; i<n; i++) {</pre>
  // do something
  if (/* some condition */) {
    for (int j=0; j<n; j++) {</pre>
      // do other stuff
// clean up
```

- Time complexity now depends on the if statement
- If the condition is often satisfied we have a $\Theta(n^2)$ algorithm
- If the condition is true only rarely then we have a $\Theta(n)$ algorithm

BIOM2005

Precise Definitions of O(n)

• An algorithm that runs in f(n) operations is O(q(n)) if

$$\lim_{n\to\infty}\frac{f(n)}{g(n)}=c\qquad \text{ where }c\text{ is a constant (could be zero)}\blacksquare$$

• E.g.. $f(n) = 3n^2 + 2n + 12$

$$\lim_{n \to \infty} \frac{f(n)}{g(n)} = \lim_{n \to \infty} \frac{3 \, n^2 + 2 \, n + 12}{n^2} = 3 \mathbb{I} \ \, \Rightarrow 3 \, n^2 + 2 \, n + 12 = O(n^2) \mathbb{I}$$

$$\lim_{n \to \infty} \frac{f(n)}{g(n)} = \lim_{n \to \infty} \frac{3n^2 + 2n + 12}{n^3} = 0 \implies 3n^2 + 2n + 12 = O(n^3)$$

$$\lim_{n \to \infty} \frac{f(n)}{g(n)} = \lim_{n \to \infty} \frac{3n^2 + 2n + 12}{n} = \infty \blacksquare \Rightarrow 3n^2 + 2n + 12 \neq O(n) \blacksquare$$

BIOM2005

Lower Bound Definition

Big-Theta

• An algorithm that runs in f(n) operations is $\Omega(g(n))$ if

$$\lim_{n\to\infty}\frac{g(n)}{f(n)}=c\qquad \text{ where }c\text{ is a constant (could be zero)}\blacksquare$$

• E.g. $f(n) = 3n^2 + 2n + 12$

$$\lim_{n \to \infty} \frac{g(n)}{f(n)} = \lim_{n \to \infty} \frac{n^2}{3 \, n^2 + 2 \, n + 12} = \frac{1}{3} \implies 3 \, n^2 + 2 \, n + 12 = \Omega(n^2) \blacksquare$$

$$\lim_{n\to\infty}\frac{g(n)}{f(n)}=\lim_{n\to\infty}\frac{n^3}{3\,n^2+2\,n+12}=\infty \mathbb{I} \Rightarrow 3\,n^2+2\,n+12\neq\Omega(n^3)\mathbb{I}$$

$$\lim_{n \to \infty} \frac{g(n)}{f(n)} = \lim_{n \to \infty} \frac{n}{3n^2 + 2n + 12} = 0 \quad \Rightarrow 3n^2 + 2n + 12 = \Omega(n)$$

BIOM2005 Further Mathematics and Algorithms BIOM2005

Further Mathematics and Algorithms

Use and Misuse

- Note: big-O notation is most commonly used
- often people say they have a $O(n^2)$ when in fact they mean they have a $\Theta(n^2)$ algorithm (a much stronger result)
- Note that an $O(n^2)$ algorithm is also a $O(n^3)$ algorithm
- Strictly a $O(n^2)$ algorithm may not be faster than a $O(n^3)$ algorithm when n becomes larger
- A $\Theta(n^2)$ algorithm will be faster than a $\Theta(n^3)$ algorithm when n becomes larger

• An algorithm that runs in f(n) operations is $\Theta(q(n))$ if

$$\lim_{n\to\infty}\frac{g(n)}{f(n)}=c\qquad \text{where }c\text{ is a non-zero constant}$$

• That is, $f(n) = \Theta(q(n))$ if

$$f(n) = O(g(n)) \quad \text{and} \quad f(n) = \Omega(g(n)) \blacksquare$$

- I.e. the lower bound is identical to the upper bound
- Often the most straightforward way of obtaining big-Theta is to show the upper and lower bounds are the same

Lessons to Learn

- Run times (computational time complexity) matters
- Choosing an algorithm with the best time complexity is important.
- Understand the meaning of big-Theta, big-O and big-Omegal
- Know how to estimate time complexity for simple algorithms (loop counting)
