1. Equivalent Classes

2. Disjoint Sets

3. Fast Sets

Equivalence Relations

• Given a set of elements $\mathcal{X} = \{x_1, \, x_2, \, \ldots\}$ and a binary relationship \sim with the following properties

(Reflexivity) For every element $x\in\mathcal{X}$, $x\sim x$ (Symmetry) For every two elements $x,y\in\mathcal{X}$ if $x\sim y$ then $y\sim x$

(Transitivity) For every three elements $x,y,z\in\mathcal{X}$ if $x\sim y$ and $y\sim z$ then $x\sim z$

ullet Then \sim defines a partitioning of the set into **equivalence classes**

Algorithms and Analysi

Dynamic Equivalence Classes

- Finding equivalence classes is rather easy using graph traversal algorithms
- However, as our web example suggests, there are applications where equivalence classes change over time!
- Adding a link could join two domains which were separate
- We will see this is a useful idea both for building mazes and (in a later lecture) for finding minimum spanning trees!
- Building a data structure which finds equivalence classes where the equivalence relation changes over time is challenging but fortunately there is an elegant solution to this

AICE1005

Algorithms and Analysis

Union-Find

- In the union-find algorithm we have a set of objects $x \in \mathcal{S}$ which are to be grouped into subsets $\mathcal{S}_1, \mathcal{S}_2, \dots$
- Initially each object is in its individual subset (no relationships)
- We want to make the union of two subsets (add relationship between elements)
- We also want to **find** the subset given an element
- This is a common problem for which we will write a class
 DisjointSets to perform fast unions and finds

Example of Equivalence Classes

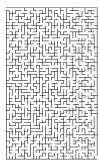

- Although, equivalent classes sound very mathematical they often provide a useful formalisation of the real world
- E.g. Pairs of web pages with a link in each direction between them
- Consider web pages in the same equivalence class if you can get from one to the other by clicking links
- Partitions the web into linked domains
- Friendship relations in social media

- 2. Disjoint Sets
- 3. Fast Sets

AICE1005

Algorithms and Analysis

DisjointSets

We want to create a class public class DisjointSets

```
public DisjointSets(int numElements) {/* Constructor */}
public int find(int x) {/* Find root */}
public void union(int root1, int root2) {/* Union */}
```

- private int[] s;
- Where find (x) returns a unique identifier for the subset which element x belongs to
- The array s contains labelling information to implement find (x)

ICE1005 Algorithms and An

AICE10

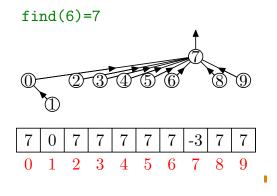

Algorithms and Analysis

The Union-Find Dilemma

- A natural algorithm to perform finds is to maintain an array returning a subset label for each element—this makes find fast
- However, every time we combine two subset we have to change all the labels in this array (taking O(n) operations)
- If we are unlucky the cost of performing n unions is $\Theta(n^2)$
- If we ensure that we relabel the smaller subset then the time complexity is $\Theta(n \log(n))$
- Fast finds seems to give slow(ish) unions
- What about the other way around?

AICE1005

Putting it Together

AICE1005

Path Compression

• To speed up find we relabel all nodes we visit during find by the root label

```
public int find(int index)
      (s[index]<0)
       return index;
       return s[index] = find(s[index]);
  }
s[] 10 20 -3
```

AICE1005

Time Complexity of Union-Find

- ullet If we perform M finds and N unions then the time complexity is $O(M \log_2^*(N))$
- \bullet Where $\log_2^*(N)$ is the number of times you need to apply the logarithm function before you get a number less than $1 \blacksquare$
- In practice $\log_2^*(N) \le 5$ for all conceivable N

• The proof of this time complexity is rather involved

Fast Union

- To achieve fast unions we can represent our disjoint sets as a forest (many disjoint trees)
- Every time we perform a union we make one of the trees point to the head of the other tree!
- The cost of find depends on the depth of the tree!
- To make unions efficient we make the shallow tree a subtree of the deeper tree!

Smart Union

```
public DisjointSets(int numElements)
     = new int[numElements];
    for(int i=0; i<s.length; i++)</pre>
                                    // roots are negative number
       s[i] = -1;
public void union(int root1, int root2)
    if (s[root2] < s[root1]) {
                                    // root2 is deeper
       s[root1] = root2;
                                    // make root2 the root
    } else {
       if (s[root1] == s[root2])
       s[root1]--;
s[root2] = root1;
                                    // update height if same
                                    // make root1 new root
s[] -A -B
                     root
```

Mazes

- Union-Find is a data structure which can occur in very different applications
- One application is building a mazel
- Start from a complete lattice

AICE1005

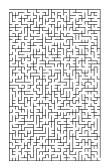

- Remove a randomly chosen edge if it connects two unconnected regions
- Stop when the start and end cell are connected
- Or better after all cells are connected

- 3. Fast Sets

Comparison of Sets

What Set to Use?

- Binary Search Trees: $O(\log_2(n))$, general purpose
- Hash tables: O(1), but need to compute hash, slow iterator when sparse, general purpose
- \bullet B-trees: $O((k-1)\,\log_k(n))$ very complicated, used for large amounts of datall
- \bullet Tries: $O(\log_k(n))$ for large k expensive in memory, complicated to code efficiently \blacksquare

AICE1005 Algorithms and Analysis 1

Bounded Set

- One special feature is that we knew we only wanted the set to contain integers between 0 and n (where n might be 100 000)
- This allowed us to use an array to represent whether an integer belong to that set!
- But how do we find a random element of the set quickly?
- Use another array of course!

 A PhD student and I were working on writing a fast solver for a combinatorial optimisation problem

- We had to choose one variable to change out of a small number of possible variables
- Each time we changed a variable then we had to update the list of possible variables (remove some variables add others)
- We wanted a data structure which had quick add and remove and where we could choose a variable at random
 what should we use?

AICE1005 Algorithms and Analysis 18

FastSet

1940 (9) (9)

_0	1	2	3	4	5	6	7	8	9
-1	-31	-1	-1	-0	-1	-1	-21	-1	-11
4	9	7	1						

05 Algorithms and Analysis 19

Implementation

```
public class FastSet extends AbstractSet<Integer> {
    private int[] indexArray;
    private int [] memberArray;
    private int noMembers;

public FastSet(int n) {
        indexArray = new int[n];
        memberArray = new int[n];
        for(int i=0; i<n; i++) {
            indexArray [i] = -1;
        }
        noMembers = 0;
}

public int size() {
        return noMembers;
}</pre>
```

Algorithms and Analysis 21

Collection Methods

```
public void clear() {
   for(int i=0; i<noMembers; i++) {
      indexArray[memberArray[i]] = -1;
   }
   noMembers = 0;
}

public boolean isEmpty() {
   return noMembers==0;
}

public Iterator<Integer> iterator() {
   return new FastSetIterator();
}
```

AICE100

Algorithms and Analysis

Add and Remove

```
public boolean add(int i) {
   if (indexArray[i]>-1)
        return false;
   memberArray[noMembers] = i;
   indexArray[i] = noMembers;
   ++noMembers;
   return true;
}

public boolean remove(int i) {
   if (indexArray[i]=--1)
        return false;
   --noMembers;
   memberArray[indexArray[i]] = memberArray[noMembers];
   indexArray[memberArray[noMembers]] = indexArray[i];
   indexArray[i] = -1;
   return true;
}
```

AICE1005 Algorithms and Analysis 22

Iterator

AICE1005 Algorithms and Analysis 23 AICE1005

Algorithms and Analy

24

And Random?

- So far we have just implemented a new Set<Integer> as part of the java Collection class
- We can add additional methods taking advantage of the classes strength

```
private static Random rand = new Random();
public int getRandomElement() {
    return memberArray[rand.nextInt(noMembers)];
}
```

• Need to use FastSet signature to use this

```
FastSet fastSet = new FastSet(n);
:
int r = fastSet.getRandomElement();
```

AICE1005

Algorithms and Analy

Lessons

- If you have a bounded set then using an array is usually going to be very fast O(1) (or $O(\log^*(n))$)
- These data structures are not general purpose for solving every day problems (c.f. List<T>, Set<T> and Map<T>)
- They are "back pocket" data structures that solve problems that come up often enough that they are worth knowing about
- Sometimes good algorithms are not documented, but it doesn't mean they don't exist.

AICE1005

Algorithms and Analysi

Speed Up

- We compared our algorithm to a very highly regarded "state-of-the-art" algorithm
- For large problems we were over 10 times faster because of this data structure!
- The competitor algorithm used a complex tree structure instead of the simple array
- Why? The array solution isn't in the books
