# Outline

# Lesson 30: Understand Time Complexity

Theta, Big-O, little-o, Big-Omega, little-omega

AICE1005

Algorithms and Analysi

## Recap

- We have seen many algorithms taking times of order 1,  $\log(n)$ , n,  $n\log(n)$ ,  $n^2$ , etc!
- Sometimes these are worst time, average time or best time results
- We have lots of different notations, e.g.  $O(1), \, \Theta(\log(n)), \, \Omega(n^2),$  etc.
- What does it all mean?

AICE1005

Algorithms and Analysis

# **Defining** $\Theta(g(n))$

• A function  $f(n) \in \Theta(g(n))$  if

$$\lim_{n \to \infty} \frac{f(n)}{g(n)} = c \qquad \qquad 0 < c < \infty \text{I}$$

• E.g.

$$\lim_{n \to \infty} \frac{4n^2 + 2n + 3}{n^2} = 4$$

$$\lim_{n \to \infty} \frac{5n \log(n) + 3n + 2}{n \log(n)} = 5$$

AICE1005

Algorithms and Analysis

## **Ordering Complexity Classes**

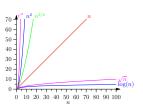

• We can define the relation  $\Theta(f(n)) < \Theta(g(n))$  if

$$\lim_{n \to \infty} \frac{f(n)}{g(n)} = 0$$

- Informally if algorithm A has time complexity  $\Theta(f(n))$  and algorithm B has time complexity  $\Theta(g(n))$  then if  $\Theta(f(n)) < \Theta(g(n))$  algorithm A is faster for sufficiently large n.
- The relation defines a complete ordering

## 1. Time Complexity Classes

- Theta $-\Theta$
- Big O
- Little o • Big Omega— $\Omega$
- Little omega— $\omega$
- 2. Computing Time Complexity

AICE1005 Algorithms and Ana

# Complexity Class Sets

- The correct way to think about complexity classes is in terms of sets
- $\bullet$  Suppose we have an algorithm which takes an input of size n and computes an output in f(n) operations
- E.g.  $f(n) = 4n^2 + 2n + 3$
- We can partition all run times into sets by considering only the leading order term and ignoring the constant term!
- $\bullet$  We denote these sets by  $\Theta(g(n)) \hspace{-.05cm} \mathbb{I}$ 
  - $\star 4n^2 + 2n + 3 \in \Theta(n^2)$
- \*  $5n\log(n) + 3n + 2 \in \Theta(n\log(n))$

AICE100

Algorithms and Analysis

#### **Ignoring the Constant**

- Does an algorithm that uses  $4n^2$  operations run faster than one that uses  $7n^2$  operations?
- Answer depends on the operations which might depend on the programming language or the machine architecture!
- ullet However asymptotically (i.e. for sufficiently large n) an order  $n\log(n)$  algorithm will always run faster than an order  $n^2$  algorithm even when they are run on different machines
- The constant is important in practice (if there are two algorithms A and B that are both  $n\log(n)$ , but algorithm A runs twice as fast as algorithm B, which one should you use?)
- Nevertheless, ignoring the constant is often essential to make analysis of algorithms doable

AICE1005

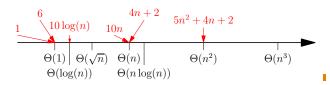

Algorithms and Analysi

## The Complexity Line

• We can order all complexity classes. E.g.

$$\Theta(1) < \Theta(\log(n)) < \Theta(\sqrt{n}) < \Theta(n) < \Theta(n^2)$$

• We can depict this as a complexity line

 The line is dense (i.e. there are an uncountable infinity of complexity classes)

# **Complexity Dependent on Inputs**

- **Unknown Time Complexity**

- The run time of many algorithms depends on the input
- In this case we can define different time complexities
  - ★ Worst case time complexity (the longest time an algorithm will take)
  - ★ Average complexity (the expected time averaged over all possible inputs)
  - \* Best case time complexity (the shortest time an algorithm will take)—usually not very interesting
- Every algorithm will have a Θ complexity class for the worst, average and best time complexity

9

## Big-O

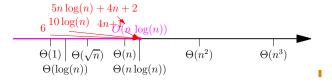

Big-O is an upper bound on the time complexity

AICE1005

AICE1005

AICE1005

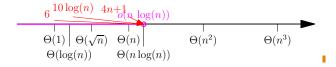

• If an algorithm is O(g(n)) then its time complexity is no more than  $\Theta(g(n))$ 

• I.e.  $\Theta(f(n)) \leq \Theta(g(n))$  implies  $f(n) \in O(g(n))$ 

#### Little-o

• Sometimes we want to say that the time complexity for an algorithm  $\Theta(f(n))$  is **strictly less** than a known time complexity  $\Theta(g(n))$ 

• I.e.  $\Theta(f(n)) < \Theta(g(n))$  implies  $f(n) \in o(g(n))$ 

Algorithms and Analysis 1

## **Lower Bounding Time Complexity**

• Returning to the program

```
// define stuff
for(int i=0; i<n; i++) {
    // do something
    if (/* some condition */) {
        for (int j=0; j<n; j++) {
            // do other stuff
        }
    }
}
// clean up</pre>
```

- We might not know how frequently the if statement is true, but we know in all cases the first for loop iterates over n
- Thus we know this algorithm is in  $\Omega(n)$ —we assume the best, but the best may never happen

- Algorithms are often rather complicated and knowing the exact time complexity (for either worst, average or best cases) might not be known
- In reality it will have some run time (e.g.  $f(n) = 3n^2\log(n) + 2n^2 n + 3 \text{) and will belong to a } \Theta \text{ time complexity set (e.g. } \Theta(n^2\log(n))) \text{ but we might not be able to calculate it!}$
- However, we can usually bound the run times of algorithms

AICE1005 Algorithms and Analysis 1

## **Upper Bounding Time Complexity**

Consider a program

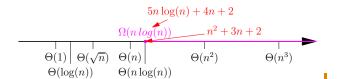

```
// define stuff
for(int i=0; i<n; i++) {
    // do something
    if (/* some condition */) {
        for (int j=0; j<n; j++) {
            // do other stuff
        }
    }
}
// clean up</pre>
```

- If the if statements is never true this is a  $\Theta(n)$  algorithm if it is always true it is a  $\Theta(n^2)$  algorithm!

AICE1005 Algorithms and Analysis 1

#### Lower Bounds— $\Omega$

- It is often easy to obtain a lower bound on an algorithm
- I.e.  $\Theta(f(n)) \ge \Theta(g(n))$  implies  $f(n) \in \Omega(g(n))$

AICE1005 Algorithms and Analysis 14

#### Little Omega— $\omega$

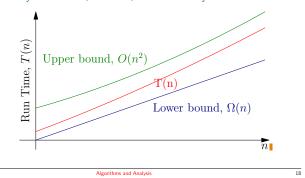

• It is sometimes useful to talk about a strict lower bound

• I.e.  $\Theta(f(n)) > \Theta(g(n))$  implies  $f(n) \in \omega(g(n))$ 

AICE1005 Algorithms and Analysis 15 AICE1005 Algorithms and Analysis

# **Bounding Run Time Complexity**

- When we are given an algorithm to analyse we want to compute  $\Theta(n)$
- This may be difficult, however, it is often easy to find bounds

# Meaning of Time Complexity

# .....

- $\star T(n) \in O(f(n))$

• If we know an algorithm is

AICE1005

- $\star \ T(n) \in \Omega(f(n)) \mathbf{I}$
- Then  $T(n) \in \Theta(f(n))$
- This is a common proof strategy

- Insertion sort has time complexity  $\Theta(n^2)$
- Because it consists of two for loops
- $\bullet$  It takes 2 seconds to sort  $100\,000$  items
- $\bullet$  How long does it take to sort  $1\,000\,000$  items?
- n increases by 10, time complexity increases by  $10^2 = 100$

Algorithms and Analysis

• Time taken is approximately 200 seconds or around 3.5 minutes

Outline

1005 Algorithms and Analysis 1

**Proving Asymptotic Time Complexity** 

# **Exponential Time Complexity**

 When we talk about exponential time complexity we usually mean that

$$\log(T(n)) \in \Theta(n) \blacksquare$$

• This is true if

AICE1005

- $\begin{array}{l} \star \ T(n) = 2^n \, \mathbb{I} \quad \log(T(n)) = n \, \log(2) \, \mathbb{I} \\ \star \ T(n) = 6.1 \, \mathrm{e}^{0.003n} \mathbb{I} \quad \log(T(n)) = 0.03 \, n + \log(6.1) \, \mathbb{I} \end{array}$
- \*  $T(n) = n \cdot 10^n$   $\log(T(n)) = n \cdot \log(10) + \log(n)$

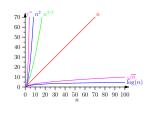

ullet Note that none of these are in complexity class  $\Theta(e^n)$ 

- 1. Time Complexity Classes
  - ullet Theta— $\Theta$
  - Big O

AICE1005

AICE1005

- Little o
- ullet Little omega— $\omega$
- 2. Computing Time Complexity

Algorithms and Analysis 2:

# Counting For Loops

• How long does the following code take?

```
for(int i=0; i<n; i++) {
    // prepare stuff
}
for(int i=0; i<n; i++) {
    // do something
    for (int j=0; j<n; j++) {
        // do other stuff
    }
}</pre>
```

- $\bullet$  The first for loop takes  $\Theta(n)$  operations the second double for loop takes  $\Theta(n^2) {\rm I\!I}$
- Answer  $\Theta(n^2)$

AICE1005 Algorithms and Analysis 2

#### Recursion

- Determining time complexity is harder when we use recursion
- Consider Euclid's algorithm for determining the greatest common divisor

• This doesn't even look like a recursion

AICE1005 Algorithms and Analysis 23 AICE1005 Algorithms and Analysis

# Example of gcd

- Example of Euclid's algorithm gcd (1989, 1590)
- Sequence of remainders is 399, 393, 6, 3, 0
- The greatest common divisor is 3
- How long does it take compute gcd(n,m) with n > m
- $\bullet$  This is subtle as could depend in a complex way on the pair n and  $m{\color{red}\mathbb{I}}$

AICE1005

Algorithms and Analysis

## **Solving Recursions**

- ullet To show that  $T(n) \in O(\log(n))$  we observe
  - $\star$  Note that T(1) = 1

$$T(n) < T(2^{-1}n) + 2 < T(2^{-2}n) + 4 < \dots < T(2^{-t}n) + 2t$$

- $\star \ \mathsf{Choose} \ t = \lceil \log_2(n) \rceil$
- \* then  $2^{-t}n = 2^{-\lceil \log_2(n) \rceil} n \le 2^{-\log_2(n)} n = \frac{n}{n} = 1$
- ★ Thus  $T(2^{-t}n) < T(1) = 1$
- $\star T(n) < 1 + 2t = 1 + 2\lceil \log_2(n) \rceil \in O(\log(n))$
- A huge calculation shows the the average number of iterations is about  $(12\log(2)\log(n))/\pi^2 + 1.47$

AICE1005

Algorithms and Analysi

## **Time Complexity**

- ullet Program involves two nested loops of size O(n)
- Then we need to calculate gcd(i, j) at each iteration
- Time complexity is  $n \times n \times \log(n) = n^2 \log(n)$
- How could we provide empirical support for this calculation?

AICE1005

AICE1005

Algorithms and Analysis

#### **Conclusions**

- You should understand the difference between  $\Theta$ , O,o,  $\Omega$  and  $\omega$
- You need to be able to compute time complexity by loop counting
- To compute time complexity for recursive functions you need to be able to obtain recurrence equations
- You should be able to solve simple recurrence equations and sum up simple series
- You should be able to prove more complicated results using proof by induction
- Thank you for attending the course

# Recursive Formulae

- An observation which makes the analysis relatively simple is that the remainder is reduced by at least 2 after two iterations
- To prove
  - $\star$  Using the recursion (assuming m, n < 0)

```
\gcd(m,n)=\gcd(n,\operatorname{rem}(m,n))=\gcd(\operatorname{rem}(m,n),\operatorname{rem}(n,\operatorname{rem}(m,n)))
```

- ★ The proof follows by showing that rem(n, rem(m, n)) < n/2
- Thus T(n) < T(n/2) + 2

AICE1005

Algorithms and Analysis 20

# **Probability of Relative Primes**

 $\bullet$  Consider the following program to compute the probability of relative primes for all numbers up to n

```
public static double probRelPrime(n)
{
  int rel=0, tot=0;
  for(int i=1; i<=n; i++)
    for(int j=i+1; j<=n; j++) {
     tot++;
     if (gcd(i,j)==1)
        rel++;
    }
  return (double) rel / tot;
}</pre>
```

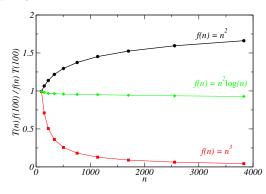

• What is the time complexity?

AICE1005

Algorithms and Analysis

## **Testing Hypothesis**

 We can test our hypothesis by scaling the run time by the complexity

AICE1005 Algorithms and Analysis
